Conditioning Event Occurrence

At the Core of Event Attribution Science

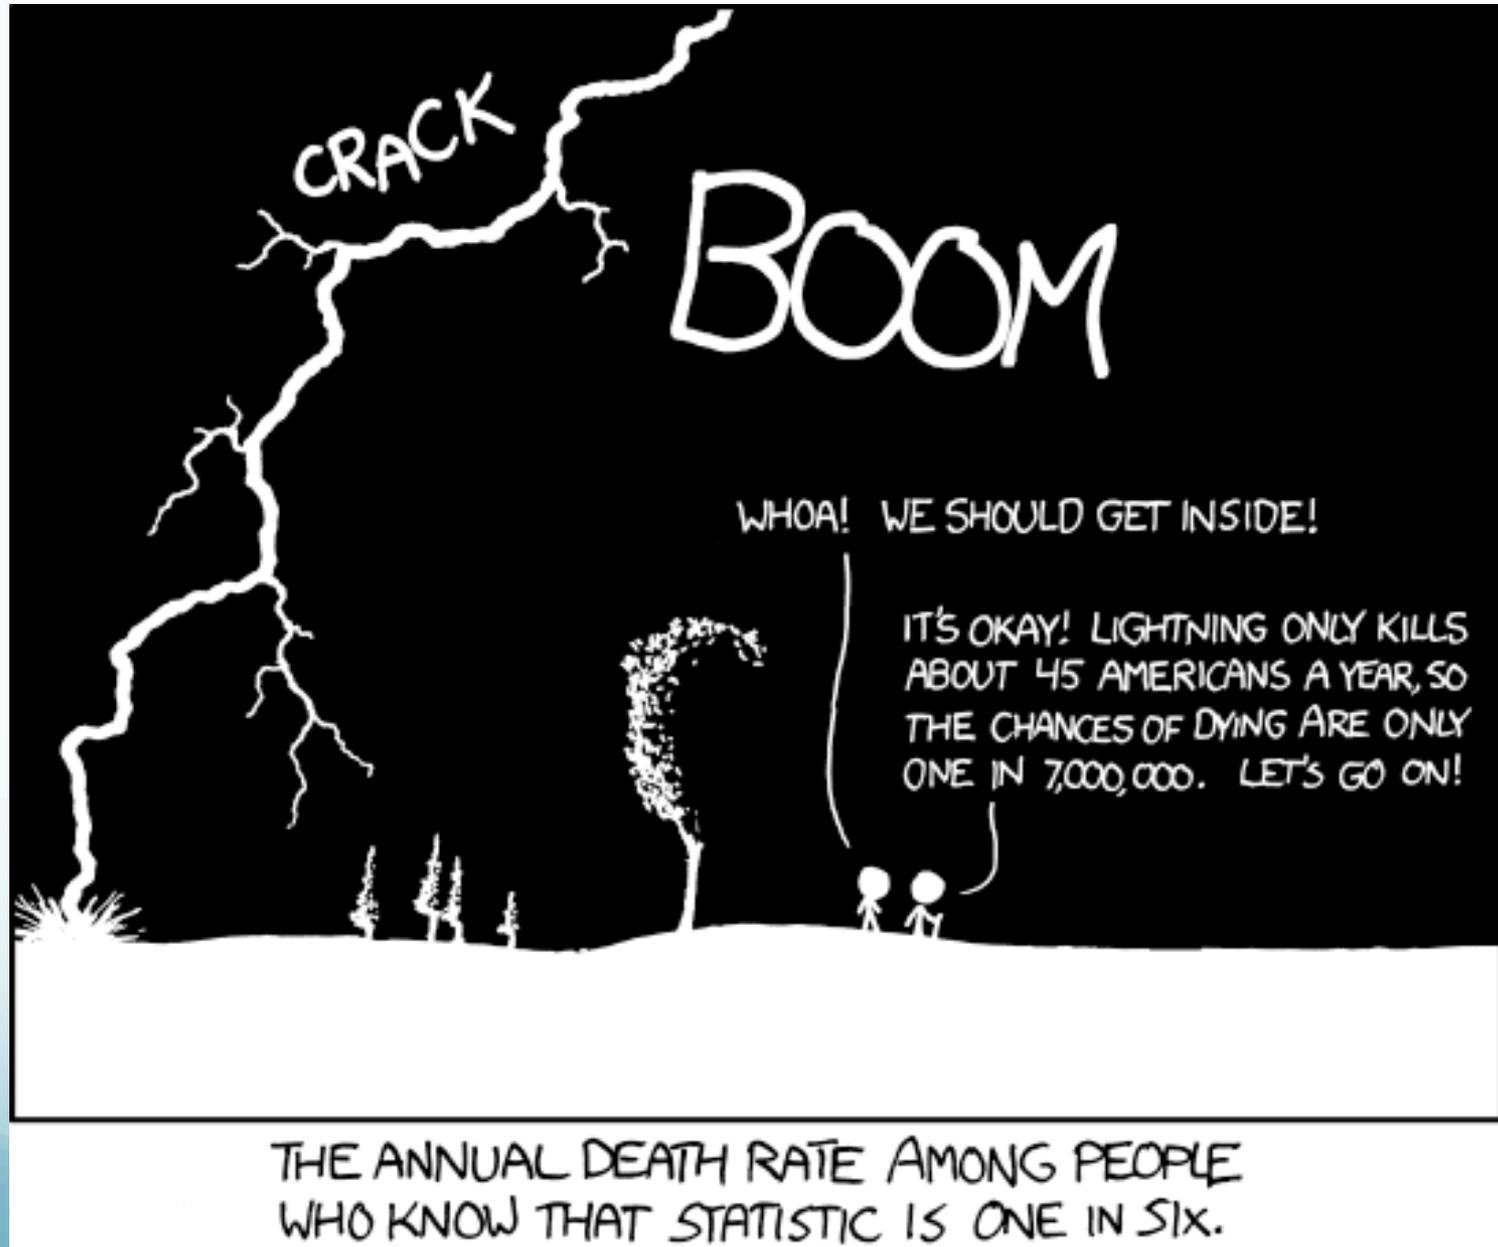

In probability theory, the **conditional probability** of A given B is the probability of A if B is known to occur (or have occurred).

$$P_B(A) = P(A \cap B) / P(B)$$

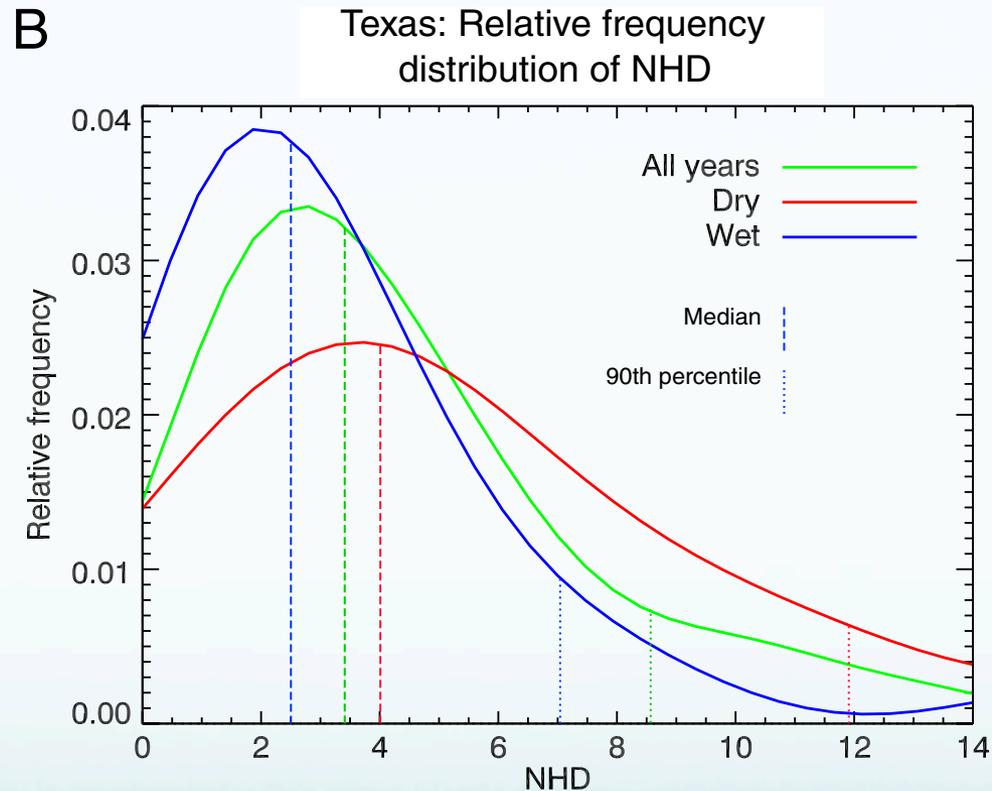

Conditional probability is so named because the ultimate chance of A occurring is conditioned on B occurring, with the practical notion (for predictive understanding) that B occurs first.

Conditional Risk

Climate Change Conditioning of Event Occurrence

A Hypothesis for Record-breaking Temperatures in a Warming Climate

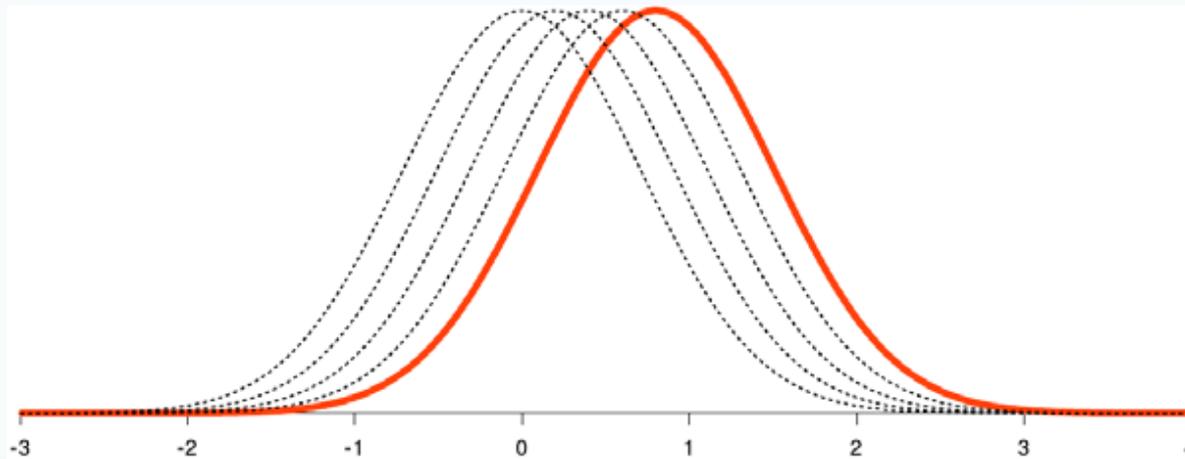

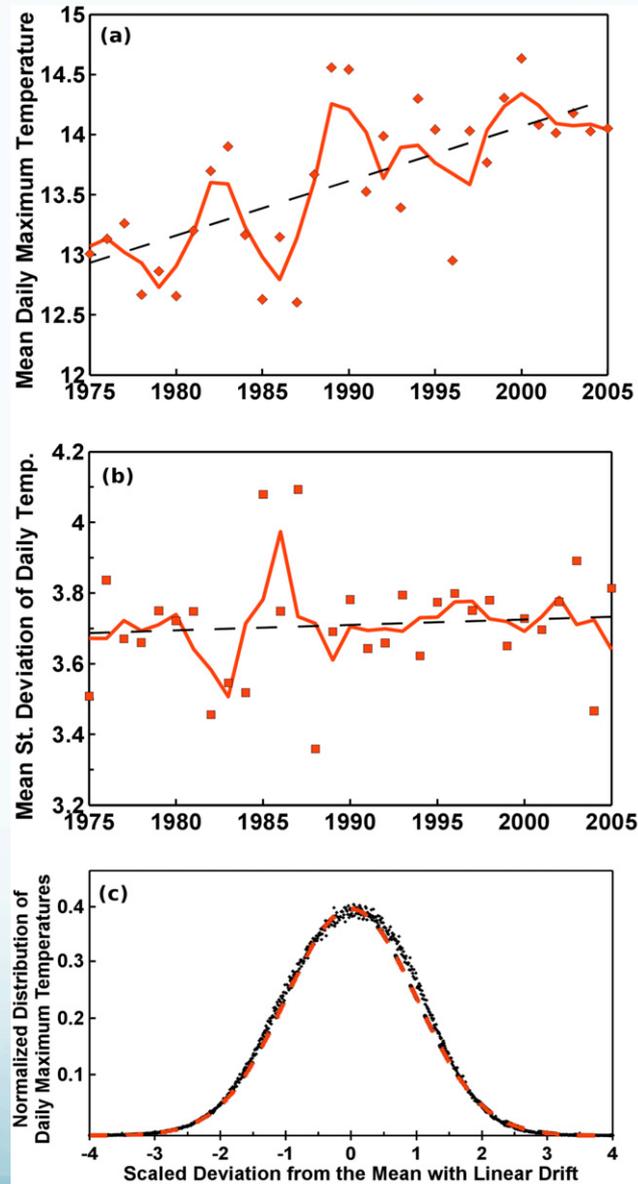

Fig. 1: (Color online) Schematic of the evolution of the daily temperature distribution under linear drift of the mean.

Wergen and Krug 2010, EPL

Characteristics of Daily Maximum Temperatures: 1975-2005

Testing Hypothesis for Record-breaking Temperatures in a Warming Climate

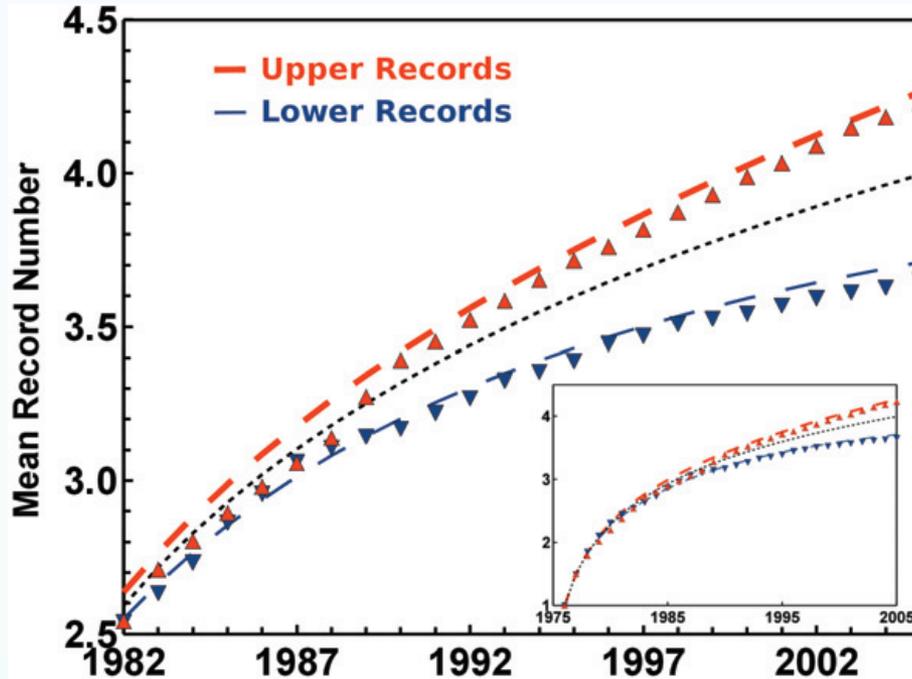

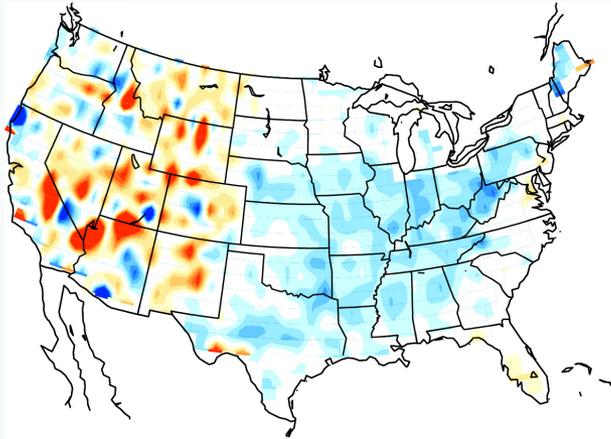

Fig. 4: (Color online) Mean record number at European stations (1976–2005). Symbols show the average number of upper (Δ) and lower (∇) records observed since 1976 at a given calendar year in the forward time analysis. The dotted line shows the prediction for a stationary climate, and dashed lines show the prediction for a constant rate of warming.
